

GW170817: The Detection of a Binary Neutron Star Merger

Duncan Brown
Syracuse University

Advanced LIGO

- The probability of a chance temporal and spatial association of GW170817 and GRB170817A is 5.0×10^{-8}
- We can confirm binary neutron stars as the progenitors of short, hard gamma-ray bursts
- The time delay between the end of the gravitational-wave signal and the start of the gamma-ray burst is $1.74 (+/- 0.05)$ s

Rapid offline re-analysis of Hanford, Livingston, and Virgo data

GCN 21513 at 1:54 pm EDT with localization...

TITLE: GCN CIRCULAR
NUMBER: 21513
SUBJECT: LIGO/Virgo G298048: Further analysis of a binary neutron star candidate with updated sky localization
DATE: 17/08/17 17:54:51 GMT
FROM: Leo Singer at NASA/GSFC <leo.p.singer@nasa.gov>

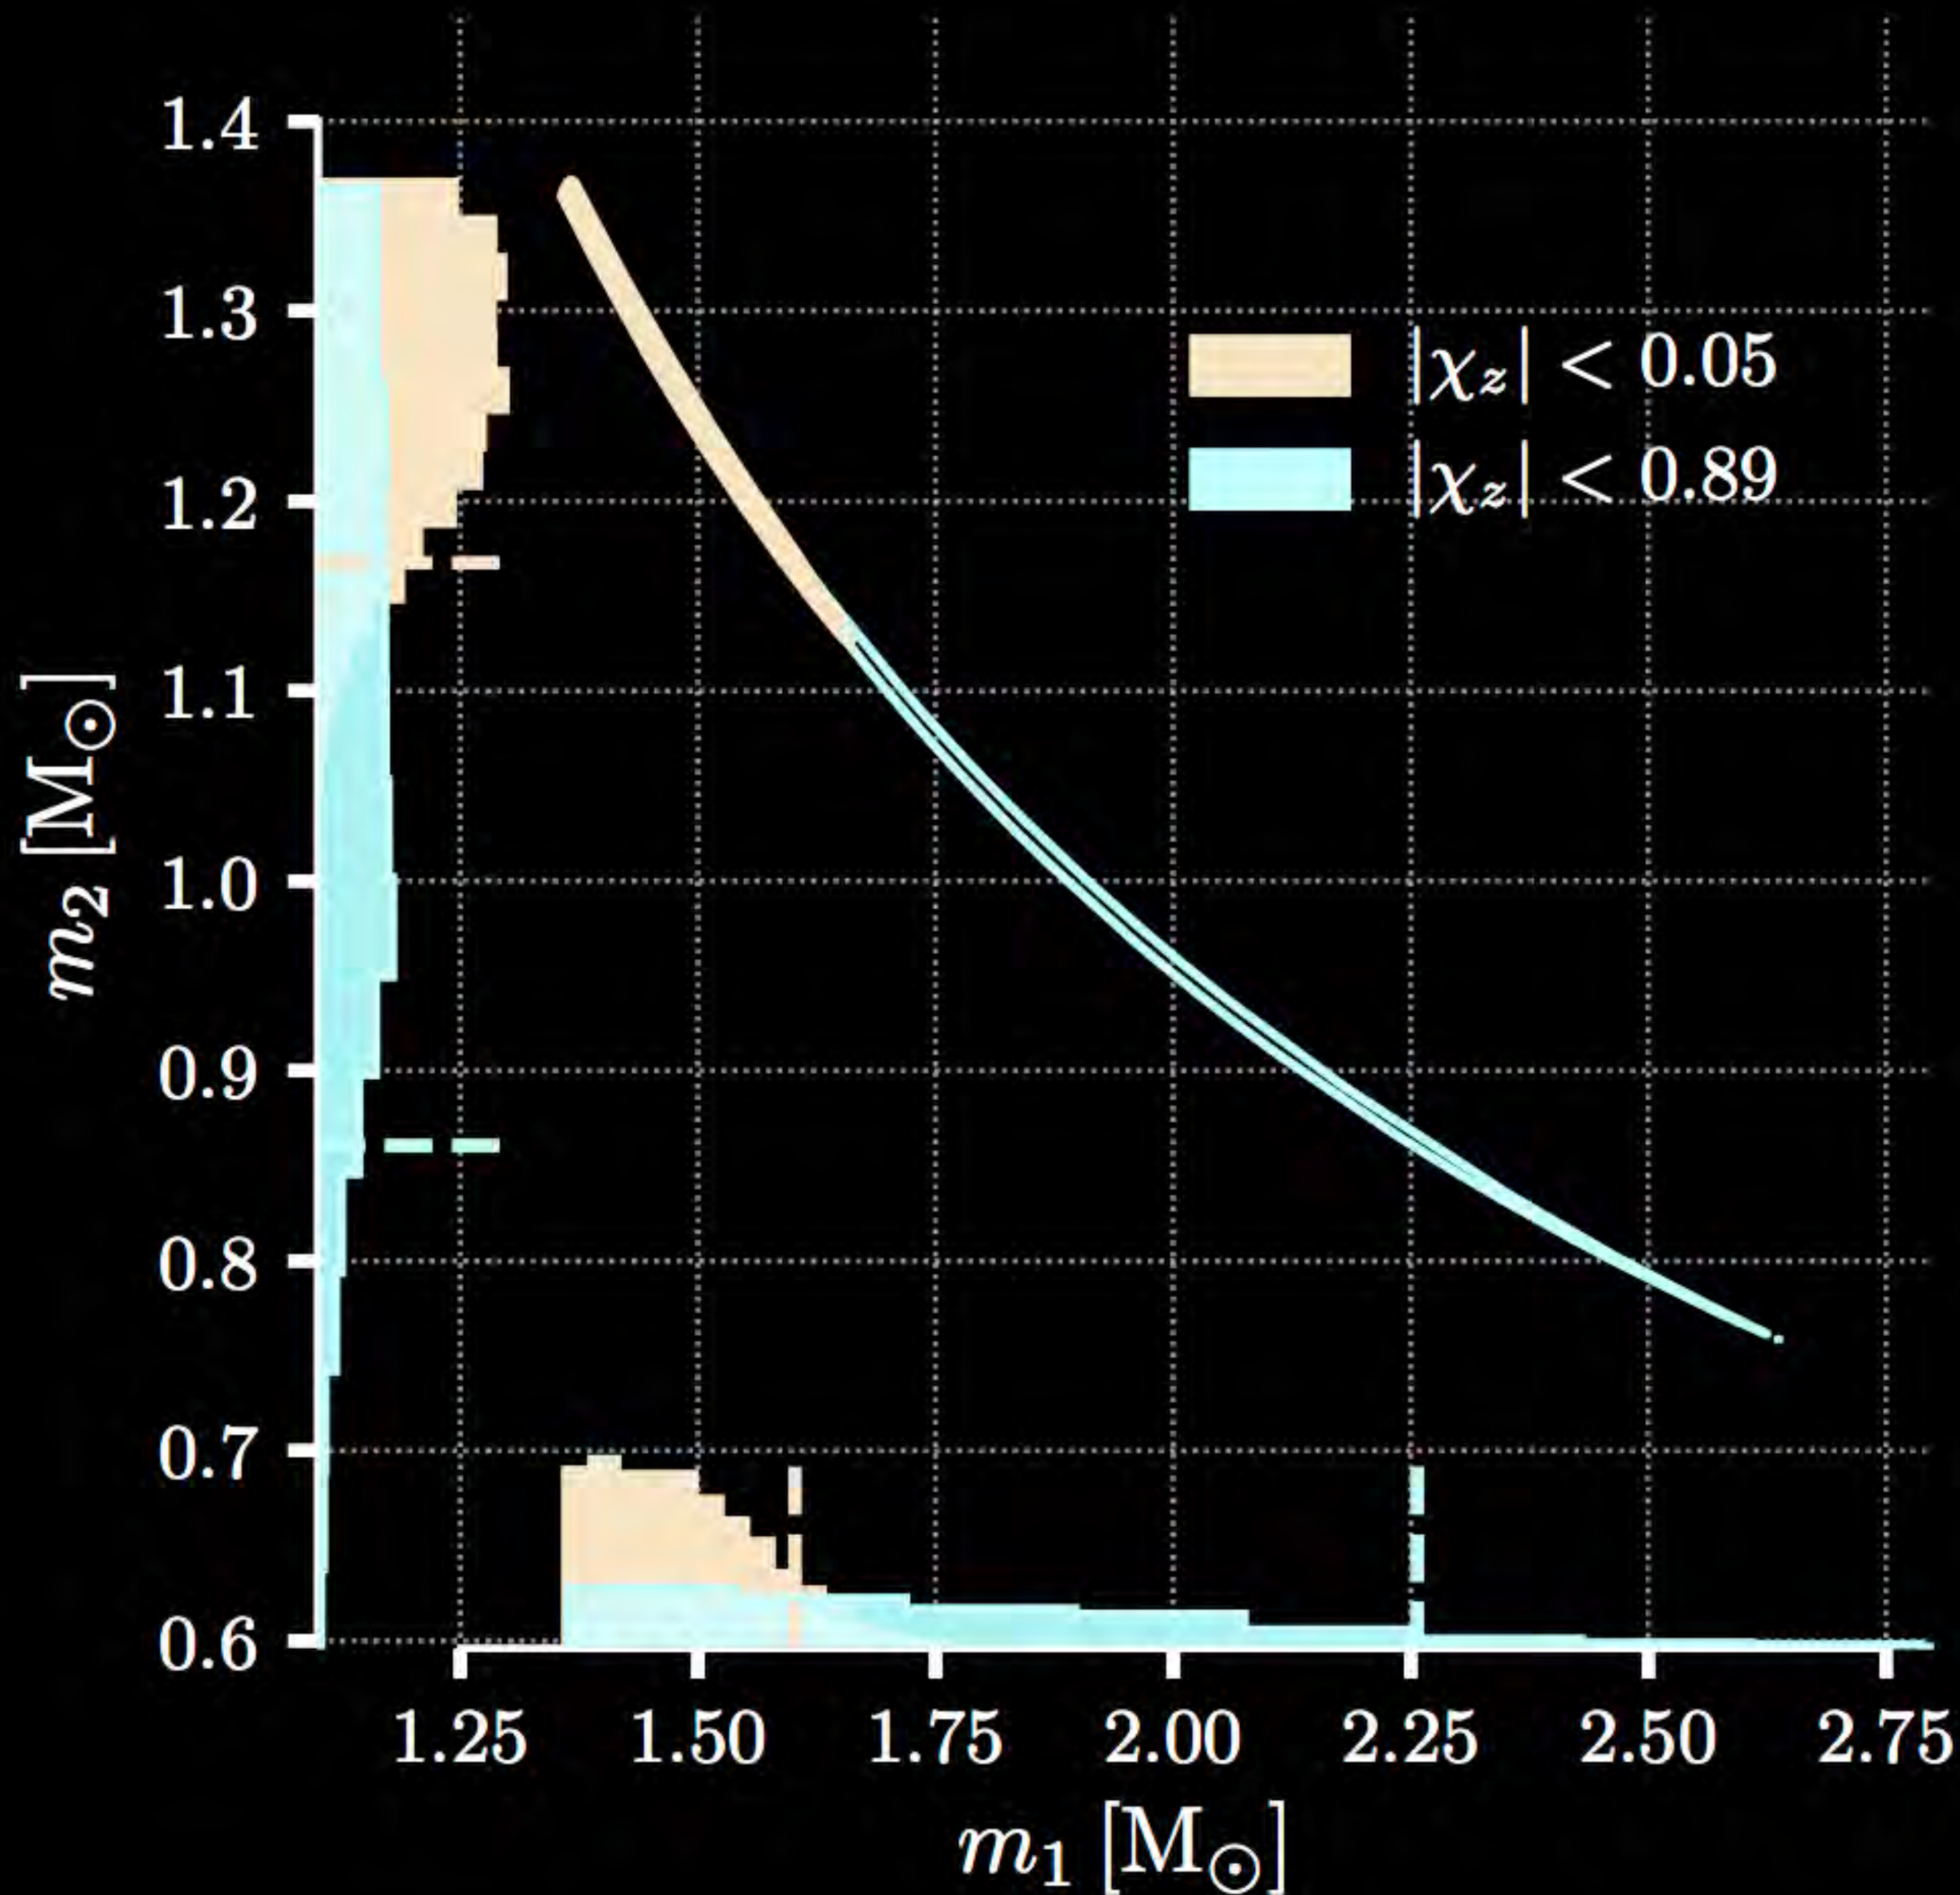

The LIGO Scientific Collaboration and the Virgo Collaboration report:

We performed a preliminary offline analysis using the PyCBC search (Nitz et al. arxiv:1705.01513, 2017) of the binary neutron star candidate G298048 (LSC and Virgo, GCN 21505, 21509, 21510) identified in low-latency by the gstlal online search (Messick et al. Phys. Rev. D 95, 042001, 2017).

A trigger consistent with a binary neutron star merger is observed at GPS time 1187008882.443 (2017-08-17 12:41:04 UTC) in both the LIGO Livingston (L1) and LIGO Hanford (H1) detectors. The trigger is below threshold in Virgo because of the antenna pattern for Virgo (V1) at the time and location of this event, but the Virgo instrument contributes to the localization. The duration of the gravitational-wave signal is approximately 74 seconds from the search's low-frequency cutoff of 27 Hz to the binary merger.

Investigation of L1 data identified a noise transient from a known class of instrumental glitches during the inspiral signal. The duration of this glitch is a small fraction of a second and does not appear to affect the signal at times away from the glitch. To make an improved preliminary estimate of the sky position, we re-analyzed the data, removing the L1 noise transient at GPS time 1187008881.389 by multiplying the strain data with a Tukey window, such that the total duration of the zeroed data is 0.2 s and the total duration of the Tukey window is 1.2 s.

An updated BAYESTAR sky map (Singer et al. 2016, ApJL 829, 15) that uses data from all three gravitational-wave observatories (H1, L1, and V1) is available for retrieval from the GraceDB page (<https://gracedb.ligo.org/events/view/G298048>): bayestar-HLV.fits.gz. The centroid (maximum a posteriori) sky location is R.A.=12h57m, Dec.=-17d51m. The 50% credible region spans about 9 deg² and the 90% region about 31 deg². The luminosity distance is 40 +/- 8 Mpc (all-sky a posteriori mean +/- standard deviation). This is the preferred sky map at this time.

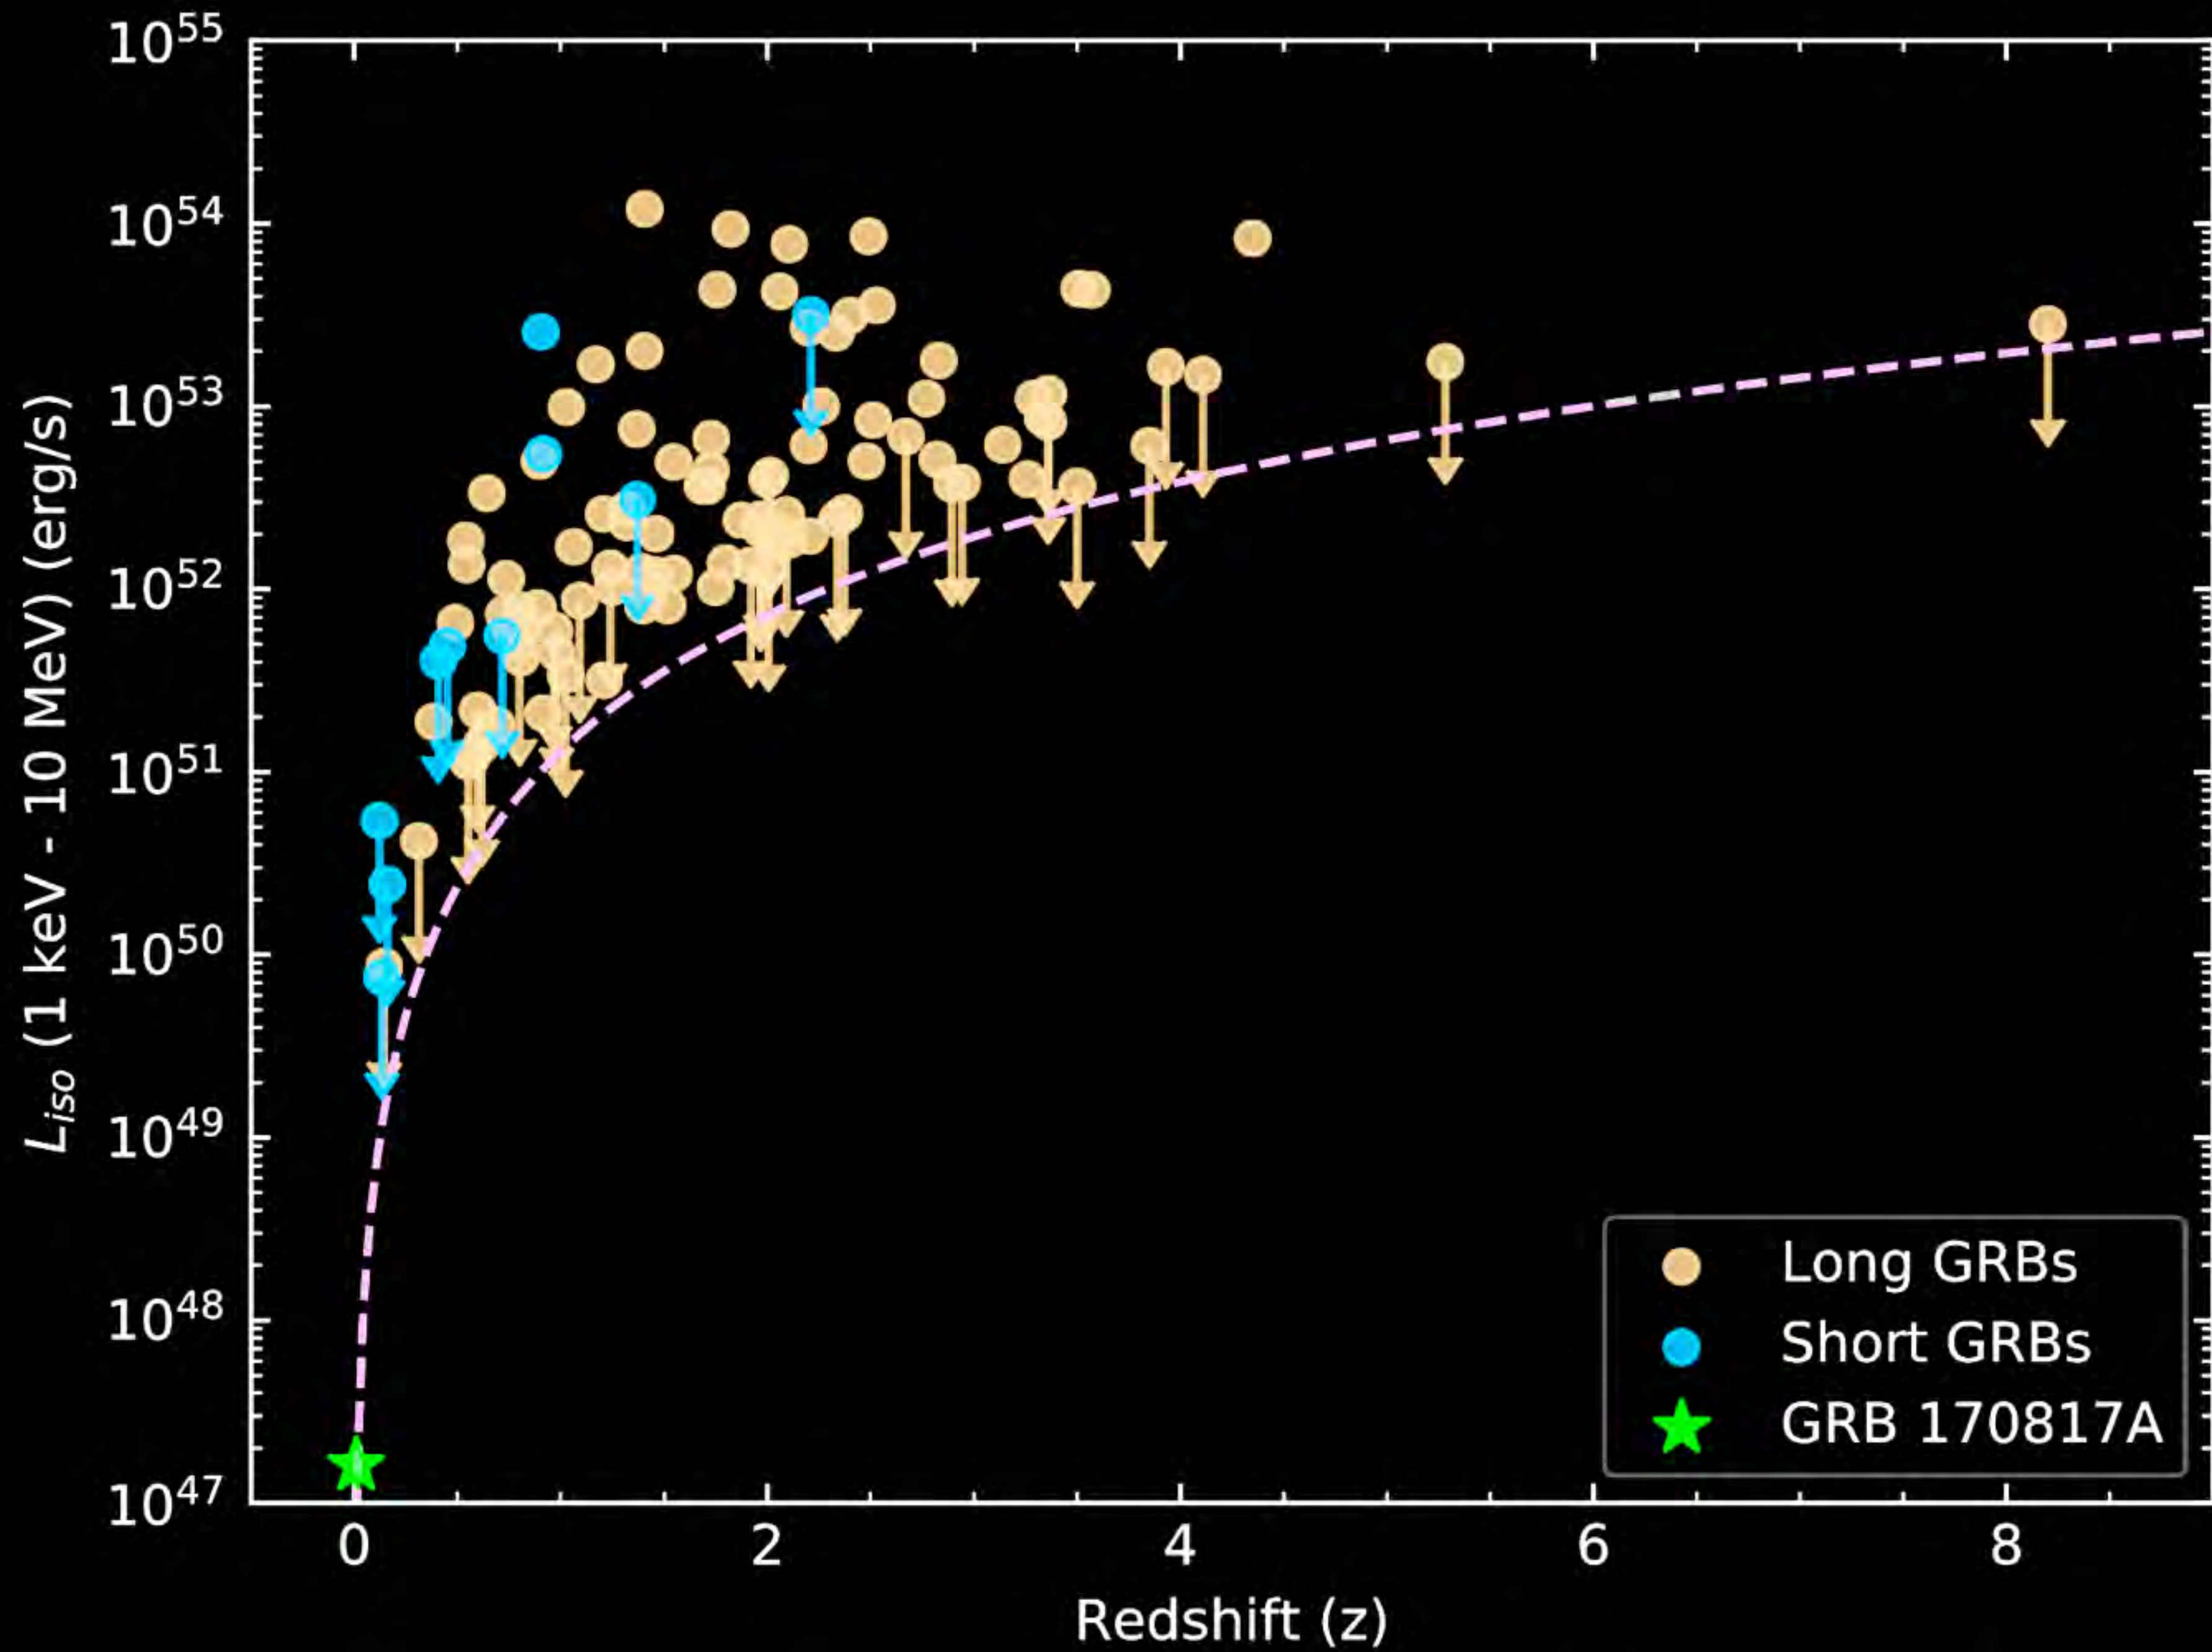

$$\chi = \frac{J}{m^2} \approx 0.4 \left(\frac{1 \text{ ms}}{T} \right)$$

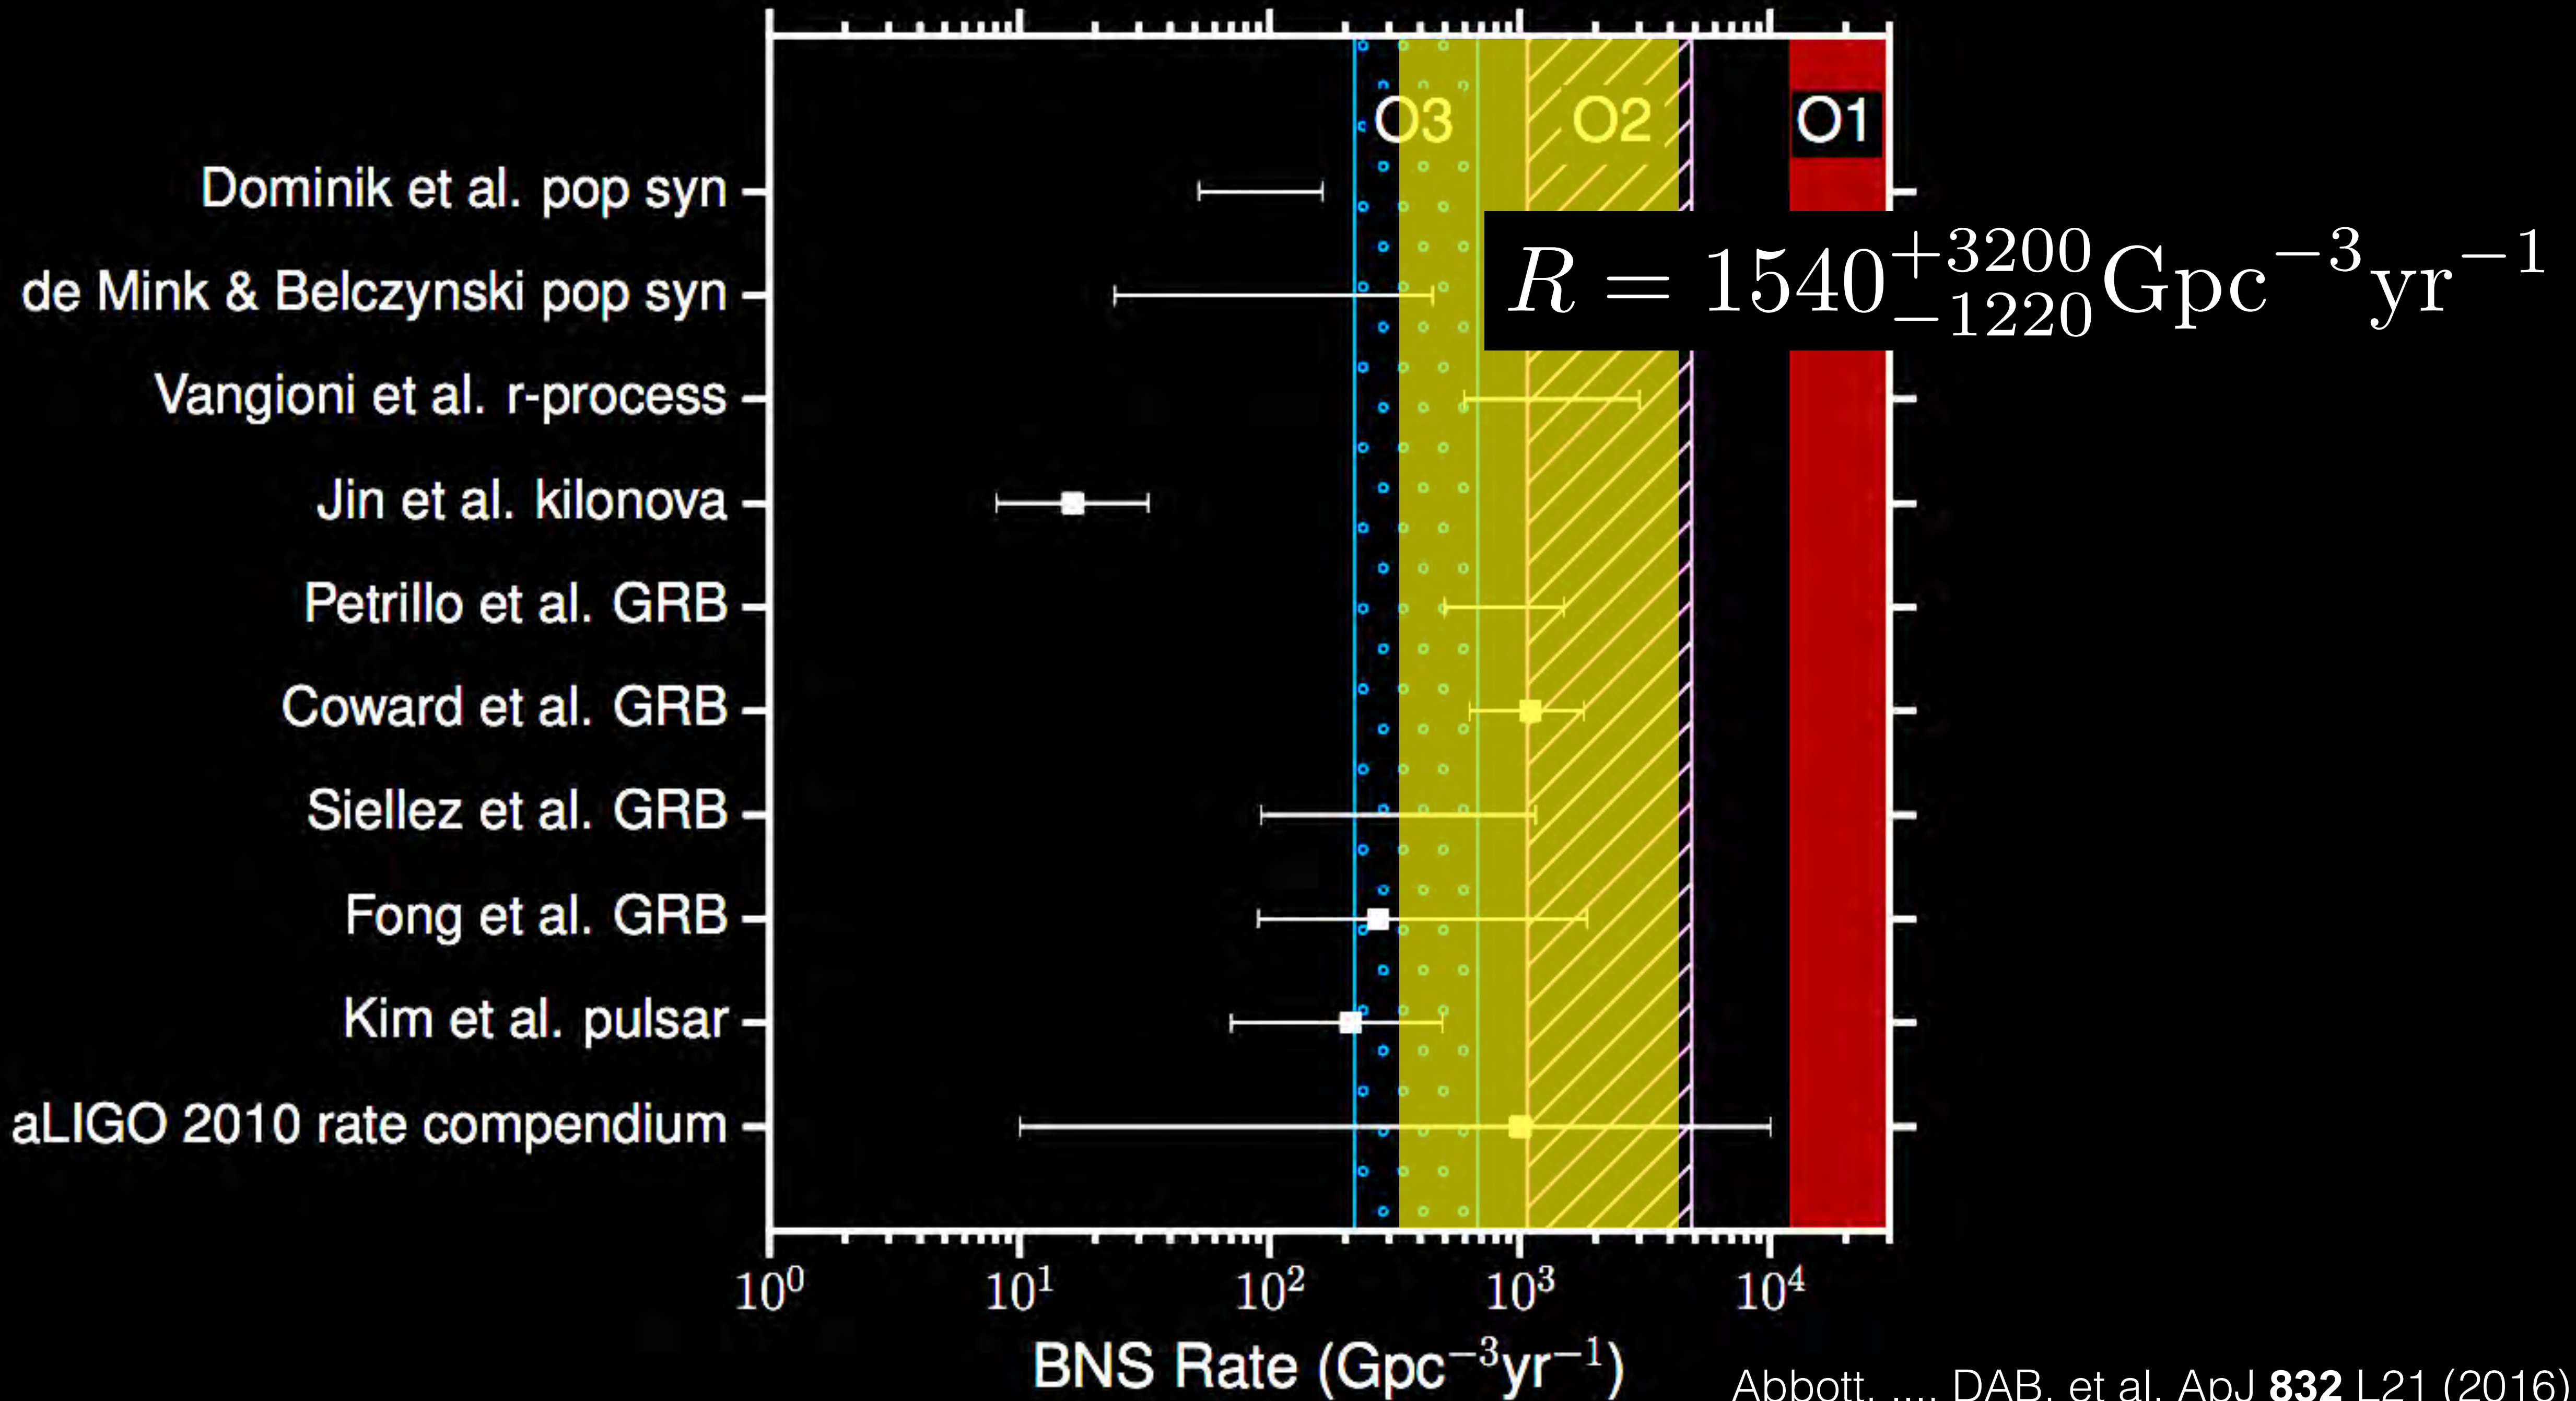

$$\mathcal{M} = \frac{(m_1 m_2)^{3/5}}{(m_1 + m_2)^{1/5}} = 1.188^{+0.004}_{-0.002} M_\odot$$

$$m_1 = 1.36 - 1.60 M_\odot \text{ (90\% credible)}$$

$$m_2 = 1.17 - 1.36 M_\odot \text{ (90\% credible)}$$

$$D_L = 40^{+8}_{-14} \text{ Mpc}$$
